

## Chemical freeze-out curve in heavy-ion collisions and the QCD critical point

*Wednesday, 25 September 2024 16:40 (20 minutes)*

The chemical freeze-out curve in heavy-ion collisions is investigated in the context of QCD critical point (CP) search at finite baryon densities. Taking the hadron resonance gas picture at face value, chemical freeze-out points at a given baryochemical potential provide a lower bound on the possible temperature of the QCD CP. We first verify that the freeze-out data in heavy-ion collisions are well described by a constant energy per particle curve,  $E/N = \text{const}$ , under strangeness neutrality conditions ( $\mu_S \neq 0$ ,  $\mu_Q \neq 0$ ). We then evaluate the hypothetical freeze-out curve based on this criterion in the absence of strangeness neutrality ( $\mu_S = 0$ ,  $\mu_Q = 0$ ) and confront it with recent predictions on the CP location. We find that recent estimates based on Yang-Lee edge singularities from lattice QCD data on coarse lattices place the CP significantly below the freeze-out curve and are thus disfavored by the heavy-ion data. On the other hand, predictions based on functional methods and holography place the CP slightly above the freeze-out curve, indicating that the QCD CP may be located very close to the chemical freeze-out in A+A collisions at  $\sqrt{s_{NN}} = 3.5 \div 5$  GeV.
